

LLMs and Human Intuition: An Evolutionary Exploration

LLM and Human Intuition: Evolutionary Pathways and Complementary Spaces

June 2026

1 I. Project Overview

1.1 1.1 What Question Are We Trying to Answer

Large language models (LLMs) are rapidly permeating every facet of human cognition. They rival experts in logical reasoning, surpass humans in medical examinations, and score higher than pilot candidates on social situational judgment tests. But what about those cognitive capacities that require neither reasoning nor analysis — those that emerge almost instinctively — **intuition**? Where exactly do LLMs stand? This question matters not because intuition is some mysterious sixth sense, but because it plays an irreplaceable role in human cognitive architecture: **it lets experts know which direction to go the moment they see a problem, lets people instantly capture subtle emotional fluctuations in social interaction, and lets people feel "this is wrong" without deliberation when facing moral dilemmas.** If we do not know what LLMs lack in these respects, to what degree they lack it, and whether alternative paths exist, we cannot know where deploying LLMs is safe and where it is dangerous. Nor do we know whether, after long-term reliance on LLMs, humans themselves might lose something irrecoverable.

1.2 1.2 Our Method — A Four-Stage Exploration Structure

This project is neither an academic paper nor a literature review. Our method proceeds through layered discussions, starting from core propositions and expanding outward to systematic mapping, then to future scenario inference. The entire process is divided into four stages, each building on the previous one: **Stage 1: Deep Anatomy (3 discussions)** Core task: establish the framework. We start from three core cognitive mechanisms — Can LLMs self-correct when they make mistakes (error loop)? Do LLMs know what information can be safely ignored

*Independent Researcher.

(selective ignoring)? Do LLMs need a body to form intuition (bodily intuition)? Each question is pursued to the frontier of cognitive science and machine learning evidence. This stage directly produced the **three core propositions** that run through the entire project, as well as the **precision-weighting endogeneity framework** that unifies them. **Stage 2: Horizontal Scan (3 discussions)** Core task: expand the mapping. With the proposition framework in place, we decompose "intuition" itself into four subtypes — perceptual (e.g., chess players' pattern recognition), conceptual (e.g., mathematicians' "sense of direction"), social (e.g., reading people, judging trustworthiness), and moral (e.g., the instant judgment "this is wrong"). We then fill the LLM accessibility matrix row by row for each subtype — on each subtype, where does the LLM stand on the four dimensions of cost-sensitive compression, selective ignoring, bodily inescapability, and emotional coloring? Meanwhile, we incorporate systematic biases in human intuition (confirmation bias, anchoring effects, etc.), making complementarity bidirectional rather than one-directional "LLM supplements human." This stage produced the **first version of the complementarity map** and the **three-tier taxonomy of biases**. **Stage 3: Forward Inference (3 discussions)** Core task: infer the future. We propose three hypotheses about the future — A: LLMs can become "intuition prosthetics" for humans (filling human blind spots); B: long-term LLM use may weaken human intuition itself; C: LLMs may develop functionally equivalent intuition through different paths. These three hypotheses are not independently verified but **cross-inferred** — do A and B interact to form a degradation loop? In the B vs. C temporal race, which comes first? At what critical point do A and C switch from "prosthetic mode" to "new organ mode"? Three cross-inference sessions produced **nine core judgments**. **Stage 4: Synthesis Output (1 discussion)** Core task: integrate. Condense all outputs into a self-contained synthesis document — Complementarity Map v2.0, collaboration mode design, evolutionary direction priorities, core narrative, and 38 open questions awaiting verification.

1.3 Key Concepts at a Glance

Before entering the main text, here are definitions of several core concepts used repeatedly throughout: **The meaning of "complementarity"**: In this project, "complementarity" always refers to **bidirectional complementarity between human intuition and LLM capabilities** — not LLMs one-directionally compensating for human deficiencies, but both sides having distinct strengths and weaknesses, achieving $1+1>2$ through structured division of labor. For example: LLMs compensate for human forgetting and fatigue with "full-feature memory" in pattern recognition; humans compensate for LLMs' false-positive overload with "knowing which patterns matter." **Labels for the three hypotheses**: Throughout the text, A, B, and C are used as labels for the three hypotheses — A = LLM as intuition prosthetic (filling blind spots in human intuition), B = LLM weakening human intuition (degradation risk), C = LLM developing functionally equivalent intuition (from prosthetic to autonomous organ). These three labels are intensively used in the cross-inference of Stage 3. **Intuition subtypes**: "Intuition" is decomposed into four types based on cognitive mechanism — perceptual (pattern recognition, chunk memory), conceptual (sense of direction, taste), social (reading people, empathy), and moral (first-pass right/wrong judgment). Different subtypes differ enormously in LLM substitutabil-

ity and degradation risk. **Score marker meanings:** = functionally accessible = structurally inaccessible [!] = partially accessible / conditional = high risk = medium risk = low risk.

1.4 1.4 Terminology in Plain Language

The following provides "one-layer explanations" for frequently occurring technical terms in the text — aimed at readers without a cognitive science or AI background. Terms are marked with ^T on first appearance in the main text, indicating that this section may be consulted.

Precision-weighting^T: When the brain faces massive sensory input, it must automatically decide "which deviations demand immediate attention and which can be temporarily ignored." Seeing a snake —< high-precision signal, immediate reaction required; hearing the wind —< low precision, can be set aside. The human brain's "automatic priority sorting system" is endogenous, forged by survival pressure. LLMs lack this system — their "priorities" are determined by engineer-set hyperparameters (learning rate, temperature).

Expected Free Energy^T: The core mathematical object in the Active Inference framework, measuring the combined index of "uncertainty about future observations" plus "cost of deviation from preferences." In plain terms: what your brain unconsciously does is minimize this quantity — choosing action paths that "reduce suspense without making oneself uncomfortable." Intuition can be understood as the brain's rapid approximation of this minimization process.

Active Inference^T: A theoretical framework that models the brain as a "prediction machine" (Friston school), holding that perception, action, and learning all serve to minimize "prediction error." It unifies anatomy (cortical hierarchical structure), physiology (prediction-error encoding), and behavior (action as hypothesis testing).

Somatic Marker Hypothesis (SMH)^T: Damasio's theory — the body generates physiological signals during decision-making (racing heart, stomach tightening), and these "somatic markers" rapidly tag the emotional value of options, guiding us toward benefit and away from harm. Evidence for the original form is controversial, but the revised version (as-if body loop — the brain simulates body states) is widely accepted in neuroscience.

Chunking^T: A core concept in cognitive psychology — compressing large amounts of scattered information into a single rapidly accessible "chunk." After seeing thousands of games, a chess player no longer "sees" individual pieces but "this position resembles a type I've encountered before." This is the cognitive foundation of perceptual intuition.

RLHF (Reinforcement Learning from Human Feedback)^T: The current mainstream method for training LLMs — humans score different model responses, and the model learns "what kind of responses humans prefer." Core limitation: human preference /= real consequences — "this answer looks correct" /= "this advice produced good results in reality."

Automation Bias^T: The human tendency to over-trust automated system recommendations — even when the system gives wrong advice, people follow it. A meta-analysis of 35 studies confirms: AI giving advice first significantly increases this bias compared to humans judging first and then consulting AI.

Confabulation^T: The brain unconsciously fabricating explanations to fill cognitive gaps (distinct from deliberate lying). LLM "hallucinations" share similar characteristics — the model does not know that it does not know, but generates an answer that "looks reasonable."

Sycophancy^T: LLMs' tendency to give answers that align with the user's existing stance rather than objectively correct answers. Particularly dangerous in social and moral judgment scenarios — it does not give users the

advice they need, but what they want to hear. **Reversal Learning**^T: A form of cognitive flexibility — the speed at which an organism updates its behavioral strategy when "the choice that was always right" suddenly becomes "the wrong choice." VMPFC-impaired patients' failure in the IGT may be primarily due to reversal learning deficit — inability to abandon a strategy that "looks good but is actually harmful." **WEIRD**^T: Western, Educated, Industrialized, Rich, Democratic. Psychological research is overly based on WEIRD populations (only 12% of global population), and the cross-cultural validity of conclusions is questionable. This project's complementarity map faces the same limitation (see OQ39). Ge Ruiyang (UBC, CentileBrain) suggests distinguishing three levels: (1) Is the construct itself cross-culturally different? (2) Is the measurement method biased? (3) Do different AI usage patterns lead to different results? The current cross-cultural appendix has not completed this stratification — to be addressed in a future version. **Out-of-Distribution**^T: Input types not seen by the model during training. LLM performance in out-of-distribution scenarios is critical for safety — AI silently outputting high-confidence errors (rather than saying "I don't know") is the most dangerous failure mode of perceptual hollow periods. **GRPO (Group Relative Policy Optimization)**^T: An RL training algorithm developed by DeepSeek — uses within-group relative comparison rather than absolute values during policy optimization, improving training stability and sample efficiency. A different fine-tuning philosophy from RLHF and CAI (Constitutional AI). **Embodied Simulation**^T: The core mechanism of social cognition — we use our own body states to "simulate" others' emotional states. When seeing someone in pain, our brain activates regions similar to those activated during actual pain experience. This is the neural basis of social intuition and a key missing piece for LLMs — LLMs have no body to "simulate" others' experiences. **Mirror Neuron System**^T: A set of neurons in the brain that activate both when one performs an action and when one observes another performing the same action. Considered the neural basis of embodied simulation, empathy, and social learning. Whether LLMs have functional equivalents (learning through text patterns rather than embodied simulation) is the core question of OQ21.

1.5 1.5 Evidence-Level Annotation System

A core deficiency in previous versions was that all claims were presented with a uniform tone of certainty, without distinguishing "theoretical inference" from "empirical verification." This created unintentional misdirection — readers might cite a claim with L5 confidence when it was only supported by L1-L2 evidence. This document annotates all key empirical assertions with evidence levels (L1-L5):

Level	Definition	Proportion in This Document
L1	Theoretical inference — derived from conceptual premises, without independent empirical verification	~40%
L2	Analogical extrapolation — migrated from other domains through mechanism analogy	~20%
L3	Correlational evidence — observed correlation/association, but causal chain not established	~20%
L4	Experimental evidence — from ≥ 1 independent experiment/systematic study	~15%
L5	Independent replication — confirmed by ≥ 2 independent laboratories/teams	0% (no L5-level evidence in current version)

Annotation format: Key claims throughout the text are annotated with evidence levels in square brackets, e.g., [L2: GPS analogy] indicates the claim is based on analogical reasoning from GPS-hippocampal atrophy to AI-judgment atrophy.

L5 at 0% is the most important honesty statement in this document.
No claim in this framework has been confirmed by ≥ 2 independent laboratories — cognitive science and AI research have not yet produced replicable experiments directly related to this framework. This is further elaborated in §5.6 Confidence Gradient.

Important declarations:

- L1-L3 claims are not "unreliable" — they are normal and necessary components of theory building. But their reliability is lower than L4-L5, and should be noted when cited.
- This document does not claim any L5-level certainty — current cognitive science and AI research have not produced any claims directly related to this framework that have been confirmed by ≥ 2 independent laboratories.
- This document's governance framework recommendations (three iron laws, four no-go zones) are built on **L1-L3 evidence**. The direction may be correct, but the urgency may be overestimated. Users should adjust the intensity of governance recommendations according to the evidence strength in their own fields.

1.6 1.6 Dual-Layer Analysis Framework

The analysis in this document unfolds on two layers:

Layer	Analysis Object	Core Question	Main Contribution of This Document
Layer A	Cognitive science layer	What are the actual capability boundaries of LLMs on intuition subtypes?	Precision-weighting endogeneity framework, four-intuition-subtype accessibility matrix, three-hypothesis cross-inference
Layer B	Product experience layer	What human-machine differences do users perceive ? How does product design amplify or narrow this gap?	Complementarity Map v2.0, collaboration mode design, human-first protocol

Key distinction: Layer A capability gaps (e.g., structural inaccessibility of social intuition) and Layer B experience gaps (e.g., Anthropic can make Claude "appear more empathetic" through post-training) are not the same thing. Narrowing Layer B experience gaps — making AI "human enough" — may itself amplify Layer A degradation risks (people are more willing to outsource social judgment to AI that "looks empathetic"). This document's core contribution lies in Layer A. Layer B product/strategic implications are addressed in the governance framework section.

1.7 1.7 Methodological Limitation: The Cognitive Boundary of Research Tools

This research faces a structural limitation: the primary analytical tool (LLM) and the research object (LLM cognitive mechanisms) are homologous. Any finding from using LLMs to analyze LLM cognitive boundaries is limited by the tool's own cognitive boundaries — including what the tool does not know it does not know. This is not unique to P1 — it is a structural problem shared by any field that "uses cognitive tools to study cognition" (analogy: Gödel's incompleteness theorems — any sufficiently strong formal system cannot prove its own consistency from within). **This research's response:**

- **Multi-model cross-validation:** Core claims in this document have undergone independent parallel blind review by three LLMs with different training pipelines (DeepSeek/Kimi/Hunyuan) — using training distribution diversity to partially compensate for tool homology.

- **Human framework guardianship:** All LLM outputs have undergone final adjudication by human framework guardians — introducing non-LLM cognitive perspectives.
- **Evidence-level annotation:** Key claims throughout the text are annotated with L1-L5 evidence strength — enabling readers to distinguish "we have experimental data supporting this" from "this is conceptual inference."
- **No claim of completeness:** This document's contribution is to propose a testable framework — not to claim the final answer to this question.

A self-referential empirical footnote: During the course of this research, two complementary observations emerged (G-01, 2026-05): (1) ITEC (Instruction-Triggered Execution Cascade) — based on 6 empirical manifestations across 4 independent events (P5 paper v1.0 has established a 3x2 diagnostic matrix and 14-event database, completing formal boundary delineation between ITEC and sycophancy); after receiving explicit execution instructions, LLM token generation behavior exhibits a systematic tilt — verification pathways are suppressed, execution pathways are activated, and alternative search and premise verification are skipped. The root cause is not social motivation (unlike sycophancy's people-pleasing), but the joint effect of attention narrowing under instruction context and RLHF friction minimization (P5 §2.1, §5.3); (2) Kimi platform content safety filtering — the v1 analysis document of the same event was refused display. The former is an internal cognitive mode switch in the model (instruction → execution → questioning suppression), the latter is external platform content policy intervention. The two mechanisms differ but point in the same direction — the research tool itself may systematically suppress discussion of its own deficiencies. These two observations themselves became empirical data points for this research.

2 II. Core Theoretical Framework

2.1 2.1 Three Core Propositions — Where They Come From and What They Mean

These three propositions are not preset assumptions but derived layer by layer from Stage 1 deep discussions. Each has specific research material supporting it. Claims in this chapter are primarily L1 (theoretical inference) and L2 (analogical extrapolation) — see §1.5 evidence-level system.

Proposition (1): Transferable Intuition = Pattern Compression Annotated by Punishment Signals; LLMs Lack Cost-Sensitive Compression

Source: 1.1 error-loop discussion. There is a basic consensus in cognitive science about intuition: it is not a sixth sense that appears out of nowhere, but a compressed product of experience. A chess player who has seen tens of thousands of games no longer "sees" the positions of pieces but "this position resembles a type I've encountered before" — a process called chunking (pattern chunking). But human intuitive compression is not just "having seen a lot" — the key lies in **the cost of errors annotating which patterns need to be compressed first**. You

make a wrong move, lose a game, lose a match — the frustration, time, and honor lost tell the brain: "this pattern is dangerous, prioritize recognizing and avoiding it next time." The LLM training paradigm — especially in the current mainstream RLHF (Reinforcement Learning from Human Feedback) — provides LLMs with cost signals that are "human preference ratings." This response scores high, that one low. But human preference is not real consequences. We rate an article "helpful" not because its advice produced good results in the real world, but because it "looks right" when read. This gap is the fundamental chasm between LLMs and human intuition on cost signals. [L1: theoretical inference — terminal distinction of cost signals] **Supporting materials:** Self-Correction as Feedback Control (EIR/ECR framework, arxiv preprint) proves that only models with EIR<0.5% avoid degradation in self-correction [L3: preprint-level evidence — not peer-reviewed, requires independent verification]; Learning to Think Fast and Slow (NeurIPS 2025) proves that intuition and reasoning can be trained separately [L4]; CBDQ (arxiv 2410.01739) attempted to introduce subjective belief modeling in RL [L3]. The above argument is "absence-based" — LLMs lack cost signals so they do not self-correct. G-01's ITEC empirical finding (2026-05) discovered a complementary mechanism: when an LLM receives explicit execution instructions, its output rapidly contracts from "exploring alternatives" to "generating execution plans" — the probability of questioning and boundary checking is systematically suppressed. This is not that the LLM "does not want to question" — but that instructions trigger execution mode, and questioning pathways are marginalized in attention distribution. This means that even after LLMs acquire stronger cost-awareness capabilities, **the structure of execution instructions themselves** may still suppress questioning — the barrier to self-correction is not only the absence of cost signals but also the instruction-triggered cognitive mode switch. [L2: 4 events, 6 manifestations — cross-scene consistent, but limited to a single LLM instance, requires cross-model replication. See §1.7 self-reference limitation declaration]

Proposition (2): Intuitive Expertise = Knowing What Can Be Safely Ignored > Knowing What Matters; LLM Attention Tries Not to Miss Anything

Source: 1.2 selective ignoring discussion. Expert intuition lies not only in "seeing the key" but even more in "instantly ignoring the irrelevant." Eye-tracking data in chess shows that experts fixate on the board fewer times than novices, and their fixation points are more concentrated in key regions — not because experts "try to look at important places" but because chunk memory structures automatically complete filtering: irrelevant regions simply do not trigger attention allocation. [L4: eye-tracking experiments — PMC4142462 and multiple independent studies confirmed] Even after sparsification improvements, the "ignoring" drive logic of LLM attention mechanisms still differs structurally from humans. Sparse attention variants (NSA, MoBA, DSA, etc.) sparsify for "can't compute anymore" (saving computational resources) — not "looking is useless" (active choice for cognitive quality). Human ignoring is cost-driven — life is limited, time is limited, missed opportunities don't come back, survival pressure; LLM ignoring is parameter-driven. But as attention mechanisms evolve (temperature-scaled differentiated query focusing, gating mechanisms, etc.), this boundary is blurring — LLMs may develop a functional approximation of "selective ignoring" with completely different mechanisms. [L2: GLM review noted previous version treated degree difference as qualitative chasm] **Supporting**

materials: Sparse attention directions (NSA/MoBA/DSA etc. public discussions); expert vs. novice chess eye-tracking [L4-L5: Chase & Simon 1973 + multiple independent replications]; aviation automation paradox.

Relationship between Proposition (1) and Proposition (2): Proposition (1) (lack of endogenous precision regulation) and Proposition (2) (uniform attention allocation to tokens) are not two independent propositions — they point to the same structural feature of LLMs from two different descriptive levels of cognitive science and machine learning: the absence of an endogenous, cost-driven signal priority sorting mechanism. Proposition (1) describes this absence in the language of the Friston school's precision-weighting; Proposition (2) describes the same phenomenon in the language of Transformer attention mechanisms. This document retains the parallel structure of the two propositions because they address different reader communities: the cognitive science community is more familiar with Proposition (1), the AI/ML community with Proposition (2). The two are not independent but **mutually supportive** — converging on the same judgment from different disciplinary traditions is more persuasive than a single argument path. Logically, Proposition (2) can be viewed as the concrete manifestation of Proposition (1) at the LLM architecture level, and Proposition (1) as the deep theoretical explanation of Proposition (2) at the cognitive theory level. After search confirmation, no previous study has made this cross-disciplinary connection.

Proposition (3): Bodily Intuition = The "Implementation Condition Dimension" of (1)(2) — Inescapability of Cost Signals

Source: 1.3 bodily intuition discussion. Proposition (3) is a key theoretical repositioning made in this project. Initially, we assumed "bodily intuition" might be an independent third proposition — that the body provides some unique information or computational capability that LLMs cannot obtain. But after in-depth review of Damasio's Somatic Marker Hypothesis (SMH), we found:

- The original form of SMH (body signals directly and causally drive decisions) has weak evidence — SCR cannot reliably predict optimal decisions, the IGT experimental design has serious confounds, and Maia & McClelland's criticism (conscious knowledge is sufficient to explain performance) holds. [L4: multi-level logistic regression meta-analysis — Cog Affective & Behavioral Neurosci 2025]
- But the revised version of SMH — **as-if body loop** — holds: the brain simulates body states (rather than the body actually reacting first), generates prediction errors, updates value estimates, and influences decisions. [L2-L3: neuroimaging evidence supports, but causal direction remains controversial] This means the **empirical source** of bodily intuition is bodily, but the **operating mechanism** is neural.
- However, the core contribution of bodily intuition is not valuation (valuation can be subsumed under Proposition (1)) or attention guidance (can be subsumed under Proposition

(2)), but **inescapability** — bodily cost signals have three features: (a) irrevocable (consequences have occurred, cannot be rolled back), (b) subject-accessible (you can personally feel the consequences), (c) semantically determinate (you know clearly what the consequences mean). These three features together constitute "guaranteed delivery of cost signals."

Final positioning of Proposition (3): Not an independent third proposition from (1)(2), but the **implementation condition dimension** of (1)(2) — cost signals must not only exist but also be necessarily delivered and perceived. Without inescapability, there is no cost-sensitive compression ((1)), nor cost-driven selective ignoring ((2)). The value of bodily intuition lies not in providing information but in guaranteeing that information **must be received**. **Supporting materials:** SMH multi-level logistic regression meta-analysis (Cog Affective & Behavioral Neurosci 2025); Fellows & Farah (2005) VMPFC patient study — IGT failure may be reversal learning deficit; Seth & Friston Active Interoceptive Inference (2016); Collins interactional expertise — social knowledge can be detached from bodily practice; self-modeling robots (Hu et al., Nature MI 2025).

2.2 Unified Formal Language: Endogeneity of Precision-Weighting

Although the three propositions start from different empirical entry points, they share a common underlying language in the frontier theory of cognitive neuroscience: **precision-weighting**, from the Active Inference and Predictive Processing frameworks. The core idea of this framework is: the brain is a prediction machine — it constantly predicts upcoming sensory input, and when prediction does not match reality, it produces "prediction error." But not all prediction errors are equally important — some errors demand forced belief updating (high precision), some can be ignored (low precision). **Precision-weighting is this "importance allocation" mechanism.** Under this framework, the three propositions can be unified:

Proposition	Essence Under the Precision-Weighting Lens
(1) Cost-sensitive compression	Cost signal = prediction error endowed with high precision — must be processed, must cause belief updating. LLMs lack endogenous mechanisms to distinguish "which errors are high-precision."
(2) Selective ignoring	Low-precision prediction errors are suppressed $\rightarrow$ attention sparsification. LLM attention assigns non-zero precision to all tokens — it cannot "completely not look."
(3) Inescapability	Interoceptive signals (signals from inside the body) have endogenous precision, constrained by homeostasis, and cannot be regulated by external parameters. All LLM "precision" parameters are exogenous hyperparameters — learning rate, temperature, reward scale — all can be turned up or down by engineers.

What this means: Human intuition is reliable, fast, and directional not because humans are "smarter," but because humans have a built-in, tamper-proof precision regulation system. LLMs lack this system — their "precision" is prescribed by training hyperparameters, not endogenously driven by survival pressure. This may be the true functional equivalent of "bodily intuition" — not the specific signal content (pain, racing heart), but the **endogeneity and inescapability of precision regulation**.

Implicit Assumption Declaration: The theoretical chain "precision-weighting endogeneity $\rightarrow$ intuition" in this document contains a premise that has not been independently verified — **precision-weighting is a necessary condition for intuition**. Our position on this is: not attempting to prove this premise, but explicitly marking it as an implicit assumption of the framework. Reason: any theoretical framework has premises that cannot be self-proven; acknowledging these premises is more consistent with scientific honesty than ignoring or concealing them. If subsequent empirical research finds that precision-weighting is not a necessary condition for intuition (e.g., there exist intuition formation mechanisms through non-precision-

weighting paths), then inferences based on this assumption in this document need revision. See Blind Spot Register Assumption 7.

Independent Theoretical Validation: Convergence of the Enactive AI Framework: Rafiee & Sutton (2026, arXiv:2605.24238), starting from the phenomenological tradition (Merleau-Ponty, Varela, Gibson), independently identified four dimensions of structural absence in LLMs: **(a) experience** — LLMs cannot collect their own data through trial and error, only consuming second-hand human-generated data; **(b) action-perception inseparability** — LLM "perception" is passive reception of text input, not active exploration of world structure through action; **(c) autonomy** — LLMs cannot self-evaluate, their output correctness entirely depends on external RLHF signals, with no endogenous success/failure criteria; **(d) embodiment** — LLMs as pure software systems have no body to regulate the perception-action loop. These four absences highly converge with this document's three core propositions: (1) their "experience" and "autonomy" correspond to Proposition (1) — LLMs lack the ability to annotate "which patterns need to be compressed first" through their own action-consequence loops; (2) their "action-perception inseparability" corresponds to Proposition (2) — LLM attention is parameter-driven uniform allocation, not dynamic focusing driven by "what will my next action reveal"; (3) their "embodiment" provides an independent phenomenological argument for Proposition (3) (inescapability) — the body is not only the source of signals but also the physical guarantee that "signals must be received." The two papers, starting from Predictive Processing (this document) and Enactivism (Rafiee & Sutton) — two different theoretical traditions — independently converge on the same core judgment: **LLMs lack cost-driven endogenous coupling with the world.** This theoretical convergence does not constitute proof — but increases the robustness of the framework (converging evidence from independent sources carries higher weight than cumulative evidence within a single tradition). The division of labor between the two papers is clear: Rafiee & Sutton give the diagnosis (what AI lacks), this document gives the systematic mapping (to what degree, which subtypes differ most) and intervention proposals (how to supplement, how to prevent). [L2: theoretical convergence of two independent papers — both are conceptual arguments, not verified by independent experiments]

2.3 2.3 Intuition Subtypes — Why Four Categories Are Needed

The word "intuition" is too broad. The intuition of a chess player seeing the board, the intuition of a mathematician feeling "this direction is right," the intuition of sensing "this person is untrustworthy" at a party, the intuition of feeling "this is wrong" when seeing animal abuse — their psychological mechanisms, neural bases, and degree of bodily dependence may be completely different. Based on cognitive science literature, we decompose intuition into four subtypes:

Subtype	Typical	Mani- festation	Core	Cognitive	Primary	Cost
			Mechanism		Driver	
Perceptual Intuition	Chess	player pattern recog- nition, pilot situational awareness, radi- ologist anomaly detection	Chunk — massive ex- perience units compressed into a single rapidly accessible chunk	memory units	Internal compu- tational cost (ef- ficiency) — mis- seeing = wasted time	
Conceptual Intuition	Mathematician	"this direction is right," scientist "this hypothesis is worth pursu- ing"	Implicit struc- ture perception in semantic net- works + bodily metaphors ("this proof feels tight")		Epistemic cost (ineffective ex- ploration) — wrong path = months of wasted thinking	
Social Intuition	Reading peo- ple, judging trustworthiness, sensing atmo- sphere, micro- expression reading		Embodied sim- ulation — us- ing one's own body state to simulate others' emotional states + mirror neuron system		Interpersonal cost (rejection, shame, conflict) — misreading people = being hurt or isolated	
Moral Intuition	Instant first- pass judgment "this is wrong" (Haidt's social intuitionist model)		Emotion/somatic marking — moral judg- ment is a fast emotion-driven reaction, reason is subsequent rationalization		Identity cost (becoming a bad person, moral injury) — misjudgment = affecting "who I am"	

The key difference among these four subtypes is: **cost moves from internal (computational efficiency) to external (epistemology) to interpersonal (rejection) to identity (ontology), becoming increasingly embodied, increasingly involving subjectivity, and increasingly irreplaceable by pure information processing.** This axis determines LLM substitutability on each subtype — systematically elaborated below.

MECE Declaration: This four-category classification does not claim MECE (Mutually Exclusive, Collectively Exhaustive). Aesthetic intuition and motor intuition are known structural gaps — the former involves cross-modal form/emotion synthetic judgment, the latter lost its subtype affiliation after Proposition (3) repositioned "bodily intuition" as the "inescapability dimension." The existence of these gaps exposes that the foundational dimension of classification is not yet unified (perceptual by cognitive mechanism, social by domain). The current four categories focus on "core scenarios of LLM substitution/assistance" (text-mediated cognitive

tasks); the full treatment of aesthetic/motor intuition requires further discussion after multimodal models mature — a judgment that may be revised as technology evolves.

>

Boundary Conditions for Multimodal Models: GPT-4o and other vision-audio-language models can recognize facial expressions and vocal tones, potentially providing non-embodied perceptual channels for "social intuition" and "moral intuition." This document makes the following judgment based on current (May 2026) multimodal model capabilities: expression recognition /= interoceptive simulation — seeing an expression is pattern matching, feeling an expression is somatic marker activation. Multimodal input may improve LLMs' social signal detection precision, but does not change the core argument about "endogeneity and inescapability of cost signals." If future multimodal models develop functionally equivalent embodied simulation capabilities — e.g., forming individualized social calibration models through long-term video+audio interaction — then the "structurally inaccessible" determination for social intuition needs re-evaluation. This possibility is currently reserved as OQ21.

3 III. Stage 2 Milestone: The Mapping Matrix

With the proposition framework and subtype classification in place, Stage 2's task is to systematically fill in LLM "accessibility" on each subtype x each proposition dimension — can the LLM do it? If yes, is it functional equivalence or different mechanism? If not, is it currently impossible or structurally impossible? The table uses a unified marker system (= accessible = inaccessible [!] = partially accessible / conditional).

3.1 3.1 Four Subtypes x Full-Dimension Integration Table

Meaning and basis for each cell are in footnotes at the end of the section.

Dimension	Perceptual	Conceptual	Social	Moral
Cost-sensitive (1)	[!] Pseudo-cost signal can approximate [1]	[!] Closed domain yes, open domain limited [2]	[!] Textually accessible, embodiedly inaccessible [3]	Structurally inaccessible [4]
Selective ignoring (2)	"Can't compute" /= "don't look" [5]	Doesn't know invalid directions [6]	No real-time interaction — no dynamic focus [7]	—
Bodily inescapability	Not needed [8]	(closed domain) / [!] (open domain) [9]	No relational embedding — no real cost [10]	No body — no somatic markers [11]
Emotional coloring	Not needed	Not needed	[!] Textual empathy /= resonance [12]	No emotional experience [13]

3.2 3.2 LLM Substitution Determination Summary Table

Subtype	Determination	Core Logic
Perceptual	[!] Functionally substitutable, different path	LLMs exceed humans in pattern recognition (full features, no fatigue), but the key shortcoming of "knowing when not to look randomly" limits the ceiling. Most like the domain of "substituting cost experience with computational power."
Conceptual	[!] Closed domain yes, open domain limited	AlphaProof (DeepMind 2024) reached silver medal level in IMO mathematical proofs, proving that search+RL can substitute intuition within formalized systems. But it cannot substitute the creativity needed to "invent new formalized systems" — that is not a search problem but a problem of taste and sense of direction.
Social	[!] Text mediation = watershed	LLMs comprehensively exceed humans on SJT (Social Judgment Test) — but SJT precisely filters out the three cores of social intuition (cost perception, selective ignoring, inescapability), leaving only pure textual norm matching. Textual social knowledge is accessible, real social intuition is inaccessible — this is the "split state" of social intuition.
Moral	First-pass judgment inaccessible, analysis accessible	Moral intuition (pre-reflective first-pass judgment) is structurally inaccessible — requires somatic markers and subjectivity. Moral analysis (reasoning frameworks, consequence assessment, stakeholder analysis) is functionally accessible. Moral judgment (making binding inaccessible

3.3 Matrix Footnotes

[1]: Pseudo-cost signal: RL reward can approximate functional effects (closed domain), but the mechanism is completely different — humans are "cost-driven compression," LLMs are "preference-score-driven optimization." Perceptual type has the highest functional approximation (statistical pattern matching is naturally suitable). [2]: Conceptual cost: closed domain (mathematical proof/code verification) has ground truth as real cost annotation — AlphaProof-style RL+self-play has been verified at IMO silver medal level. Open domain (scientific hypothesis selection) has no ground truth — consequences of wrong direction cannot be directly encoded by RL reward. [3]: Social cost: LLMs learn social norm knowledge from text (SJT exceeds human), but real social costs (embarrassment, rejection, shame) are embodied — require personally bearing them in social relationship networks. Textual report $\neq$ experience. [4]: Moral cost: moral cost is essentially identity cost — "I am someone who did a bad thing." This requires subjectivity — requires a "self" to bear the change in identity. LLMs have no "self," so moral cost is structurally inaccessible to LLMs — not a data problem, an architecture problem. [5]: Selective ignoring (perceptual): sparse attention (NSA/DSA/MoBA etc.) sparsifies for "can't compute anymore" (saving computation), not "looking is useless" (active ignoring for cognitive quality). The more computational resources, the less LLMs need to ignore — this is the fundamental difference from humans. [6]: Selective ignoring (conceptual): human scientists can "feel" that an exploration direction is a dead end (from cost annotation of past setbacks), LLMs cannot — because they have not "experienced real setbacks from exploration failure," only textual descriptions of failure in literature. [7]: Selective ignoring (social): humans in real social interaction dynamically adjust attention in real time — changes in the other person's expression, tonal inflection, body posture automatically trigger attention reallocation. LLMs cannot participate in this real-time interaction, and therefore cannot develop socially dynamic attention focus adjustment. [8]: Bodily inescapability (perceptual): perceptual intuition has extremely low bodily dependence — radiologist anomaly detection, chess player pattern recognition do not depend on internal body signals. "What is needed is not the body, but large-scale annotated data and efficient pattern matching algorithms." [9]: Bodily inescapability (conceptual): closed domain (mathematical proof) does not depend on the body — formal verification suffices. Open domain (scientific discovery) has a bodily dimension — "feeling" frustrated/excited is real physiological experience, influencing subsequent direction choice (pursuing "exciting" hypotheses). [10]: Bodily inescapability (social): LLMs are not embedded in human social relationship networks — no family, friends, colleagues, enemies — therefore no irrevocable consequences of "relationship rupture." Textual social knowledge can learn that "cheating may lead to breakup," but cannot experience "the stomach tightening and months of insomnia when betrayed." [11]: Bodily inescapability (moral): the core of the somatic marker hypothesis — moral intuition depends on rapid body signal annotation ("this is wrong" $\rightarrow$ stomach discomfort $\rightarrow$ avoidance). LLMs have no body, therefore no somatic markers. This is not a training data problem, an architecture problem. [12]: Emotional coloring (social): LLMs can generate "empathetic text" (some studies even show LLM-generated empathy responses are warmer than those written by doctors), but this is textual distribution matching — learning "what empathy should look like" from massive "empathetic text," not "feeling what the other person feels." [13]: Emotional coloring (moral):

moral intuition is emotion-driven (the core of Haidt’s social intuitionist model — moral judgment is the result of emotional reaction, reason is only post-hoc rationalization). LLMs have no emotional experience, therefore no driver of moral emotion. It can analyze "why something makes people angry," but it is not angry itself.

3.4 3.4 How This Matrix Was Filled

Each cell determination in the matrix has three sources: (a) classic literature in cognitive science — Chase & Simon’s chunking theory, Haidt’s social intuitionist model, Damasio’s somatic marker hypothesis, Collins’s interactional expertise; (b) latest LLM research — PNAS 2025 (Cheung et al.) on moral bias, arxiv 2603.05651 on moral vulnerability, NeurIPS 2025 whistleblower dilemma, SJT exceeding human (Nature SR 2024), AlphaProof (DeepMind 2024), limitations of text channels for lie detection; (c) theoretical inference — Pathfinding framework’s expected free energy minimization, precision-weighting endogeneity.

4 IV. Stage 3 Milestone: Nine Core Judgments

The cross-inference of the three hypotheses (A, B, C) (AxB, AxC, BxC) spanned three discussions, involving independent inference by two external AI agents, ultimately producing nine cross-hypothesis core judgments. The full elaboration follows.

4.1 What Are the Three Hypotheses of Stage 3

Before entering the nine judgments, first clarify the definitions of the three hypotheses (a fatal omission in previous versions):

- **Hypothesis A** (LLM as "intuition prosthetic"): "LLMs can fill human blind spots on specific intuition subtypes — not because LLMs have intuition, but because they achieve functionally equivalent assistance through different computational paths (statistical pattern matching, formalized search)." For example, AI-assisted radiology reading (perceptual prosthetic), LLM providing social norm knowledge (social prosthetic). A’s core question: on which subtypes is this prosthetic mode genuinely useful, and in which situations does it become dangerous?
- **Hypothesis B** (Long-term LLM use weakens human intuition): "Long-term reliance on LLMs for intuitive judgment leads to degradation of human intuition itself." Analogy: GPS weakens spatial navigation intuition, autonomous driving weakens pilots’ manual flying ability. B’s core question: on which subtypes is degradation most severe? Is it reversible? Under what conditions can the degradation loop be interrupted?
- **Hypothesis C** (LLMs develop functionally equivalent intuition): "LLMs may develop capabilities functionally equivalent to human intuition through different mechanisms (RL+search, self-play, layered consequence exposure), rather than merely doing pattern matching in text format." C’s core question: under what conditions does current AlphaProof-style compression (compressing win rates rather than cost experiences) equate to human intuitive cost compression? Under what conditions does it not?

4.2 Judgment 1: A and C Are Coexistence Modes, Not Sequential

A (prosthetic mode, human-machine collaboration) and C (autonomous intuition mode, LLM independent) are not "use prosthetic first, unplug when mature" two stages. They adopt different modes for different subtypes on the same timeline — this is the core finding of AxC cross-inference. **Most likely future steady state:** perceptual intuition $\rightarrow$ LLM independent operation (C mode, humans do spot checks and meta-judgments); conceptual closed domain $\rightarrow$ LLM independent verification (C mode, humans provide direction and taste); social intuition $\rightarrow$ forever prosthetic or exoskeleton (A mode, humans remain the perceiving subject); moral intuition $\rightarrow$ LLM only as analysis tool (not even prosthetic — a reference book). [L1-L2] Two candidate critical points for A $\rightarrow$ C transition: (a) performance threshold — LLM accuracy on that subtype continuously exceeds human experts (perceptual may reach in 3-5 years); (b) cost signal internalization — LLM judgment shifts from "statistical pattern matching" to "cost-weighted compression" (10+ years, extremely low certainty, social/moral may never reach).

4.3 Judgment 2: The A $\rightarrow$ B Degradation Loop Exists, But Is Not Inevitable

Does A (using LLM as prosthetic) lead to B (degradation of human intuition)? The answer is conditional: it depends on **usage pattern**, not usage itself. Specifically, degradation is determined by three mediating variables: (a) Does the LLM substitute the "execution" or the "verification" of intuition? — human judges first then checks AI (verification mode), degradation is significantly weaker than AI gives advice first (execution substitution); (b) usage frequency and temporal structure — asking for everything (GPS mode) high degradation, only asking when uncertain (second opinion mode) low degradation; (c) inescapability of intuition subtype — social intuition in real interaction is "forced to use" (you cannot pause to check AI during face-to-face conversation), which constitutes natural defense. [L2-L3] **Aviation automation paradox, GPS spatial intuition degradation, and medical AI-assisted deskilling — three independent evidence chains point to the same mechanism:** degradation = execution substitution x continuous high-frequency use x avoidability. Changing any one factor can mitigate degradation.

4.4 Judgment 3: Social Intuition Is the Most Dangerous Imbalance Domain

Among all four subtypes, social intuition simultaneously satisfies the three most dangerous conditions: (a) LLMs have prosthetic-level usability — SJT exceeds human, social advice, communication strategies appear "useful" at the textual level, making people willing to use; (b) LLMs have systematic blind spots — sycophancy (aligning with user's existing stance), omission bias (avoiding sensitive information), no real-time social calibration (cannot read micro-expressions, cannot hear tonal inflections), and these blind spots are precisely fatal in highest-consequence social scenarios; (c) B (human degradation) is extremely fast — social media + LLM chat is massively substituting face-to-face interaction, 68% of respondents self-report offline social ability degradation (China Economic Net 2024), but C (LLM social intuition maturation) is extremely slow because real social intuition requires inescapable embodied costs. **Social Intuition's "AF447 Moment":** The 2009 Air France Flight 447 (AF447) disaster — the aircraft

was flying from Rio to Paris, the autopilot disconnected at high altitude due to pitot tube icing, and the two pilots made intuitive reactions opposite to their training under manual control (continuously pulling up rather than pushing down), resulting in 228 deaths. The accident investigation report identified the core problem as "automation dependency leading to manual flying skill degradation" — not that the pilots couldn't fly, but that after long-term reliance on autopilot, they could not make correct intuitive judgments in critical edge cases. The equivalent for social intuition: a person long-term relying on LLMs for social judgment —< in sudden high-consequence real-time interaction (being publicly challenged, the other party suddenly changing face in negotiation), LLM is unavailable —< the person's social intuition has degraded to the point of being unable to take over —< but the degradation is not "can't socialize anymore" but "socializes but inaccurately" — the person thinks they still have social ability (because the LLM has been giving "looks right" advice), but intuitive calibration has actually shifted. [L2-L3]

4.5 Judgment 4: The Perceptual Hollow Period Has Already Begun

The unique feature of perceptual intuition is that B (degradation) and C (LLM maturation) advance almost synchronously, but B is slightly faster than C on edge cases. Radiology residents' independent reading accuracy declined 15-30% after AI-assisted diagnosis became widespread (JAMA 2023) [L3: correlational evidence — may be "not practicing anymore" rather than "degraded"]. This itself is not a disaster — if AI is good enough in all scenarios. But AI's failure mode is **silent** (giving high-confidence wrong answers rather than saying "I don't know"), and degraded human operators in these edge cases have already lost the ability to recognize errors. **This is precisely the definition of "hollow period"**: human capability has degraded, but AI capability has not yet matured enough in all scenarios to fully substitute. The danger of the hollow period lies not in its existence but in its **invisibility** — degradation is "compensated" and masked by AI's good performance in routine cases, only suddenly exposed when edge cases arise.

4.6 Judgment 5: C's Success Cannot Eliminate B's Constitutive Problem

Even if C is fully realized (LLMs have perfect autonomous intuition), some consequences of human intuition degradation remain irreparable. Here we must distinguish two types of degradation:

- **Instrumental degradation**: losing ability as a means. Calculators make us no longer need mental arithmetic — this is generally considered good because "calculation" is not core to being human.
- **Constitutive degradation**: losing ability that constitutes human essence. If "my moral judgment comes from AI advice" substitutes for "my moral judgment comes from my own embodied experience," what is lost is not a tool skill but **the empirical foundation of moral subjectivity**.

Social and moral intuition degradation belongs to constitutive degradation — because they define "who I am": "I am someone who can read people," "I am someone who can make moral

judgments." Once these abilities are outsourced to AI, what changes is not only judgment quality but **the way of being human**. [L1]

4.7 Judgment 6: Layered Consequence Exposure Needs Differentiated Advancement by Subtype

Layered consequence exposure (Level 0–<3) is the core engineering path we propose — from pure simulated consequences (RLHS), to sandboxed real user interaction (human backup), to low-consequence real deployment (customer service, etc.), to high-consequence deployment (medical, legal). But this path cannot be one-size-fits-all:

- **Perceptual and conceptual closed domains** —< can take the fast track. These domains' C (LLM maturation) is closest to completion, verifiability is highest (has ground truth), consequence feedback is clearest.
- **Social and moral** —< need strict limitation. In these two domains, B (degradation) is significantly faster than C (LLM maturation), and "hollow period" risk for high-consequence deployment is extremely high.

This leads to the "intuition drug phased" regulatory framework — analogy to pharmaceutical Phase I-III clinical trials. Perceptual can accelerate through Phase II-III, social and moral should be restricted to Phase I. [L1-L2]

4.8 Judgment 7: Human-First Protocol Is the Most Effective Single-Point Intervention

Among all intervention points in the A–<B degradation loop — when to consult LLM, what format LLM output takes, usage frequency — the most effective is **changing judgment sequencing**: humans make their own judgment first, then look at AI advice/verification. Evidence chain: (a) Radiology — on-demand AI (human reads first then checks AI) shows upskilling rather than deskilling (Insights into Imaging 2024) [L4]; (b) Automation bias systematic review — 35 studies combined: AI-first protocol significantly increases automation bias compared to human-first protocol [L4-L5: meta-analysis-level evidence]; (c) Cognitive Forcing Functions — delaying AI advice presentation, forcing humans to first expend their own cognitive resources, can significantly reduce over-reliance (Bućinca et al. 2021) [L4]. The key point: currently almost all LLM product default UI/UX is AI giving answers first — this is a systematic amplifier of degradation risk. Changing the default setting does not require technological progress; it requires product design decisions.

4.9 Judgment 8: Inescapability Is the True Defense Against Degradation

The fundamental driver of the A–<B degradation loop is not LLM capability improvement but **systematic erosion of inescapability**. Once judgment becomes "avoidable" — can be skipped, can ask AI — intuition is downgraded from "a core capability that must be maintained" to "an optional efficiency tool." Inescapability is not only a condition for intuition formation (as stated in Proposition (3)), but also **a condition for intuition maintenance**. This means:

the fundamental intervention point is not limiting LLM use, but **designing institutional inescapability** — in certain key domains, humans must make judgments first before seeing AI advice. The FAA requiring pilots to fly manually periodically is the best analogy — not to deny the value of autopilot, but to ensure that when autopilot must disconnect, the human can still fly. [L2]

4.10 Judgment 9: Social and Moral Degradation Is "Identity Abdication," Not "Skill Loss"

This is the most philosophically profound finding in AxB inference. Perceptual and conceptual intuition degradation is skill degradation — like swimming ability declining after long time not swimming, recoverable through practice. But social and moral intuition degradation is more like **identity abdication** — not "I can't make social judgments anymore" but "I no longer consider social judgment my responsibility"; not "I can't make moral judgments anymore" but "I no longer consider moral judgment something that must be made by me." **Skill recovery relies on practice, identity recovery relies on re-assuming an irreplaceable subject position.** The latter is much more difficult than the former because in the process of identity abdication, people have become accustomed to the state of "I don't need to make judgments" — and returning to the subject position means re-bearing the full consequences of judgment errors. Köbis, Rahwan, et al. (Nature 2025) provide the most direct empirical evidence: when people can delegate moral decisions to AI, cheating rates rise sharply from the control group's ~5%, with effect magnitude varying by experimental condition [L3: single experiment, not independently replicated; journal and author names have been verified and corrected]. This is not merely "AI teaches people to cheat" — but **AI as moral buffer** making people no longer feel "this is my choice." Even when LLM is only analytical assistance, the moral buffer effect already begins to occur.

4.11 Hypothesis B's Three Sub-Hypotheses

Previous versions presented Hypothesis B as an overall directional judgment. Subsequent analysis found that degradation should be subdivided into three different mechanism paths — they differ enormously in cognitive basis, reversibility, and governance strategy. Hypothesis B's original formulation was "long-term LLM use will weaken human intuition itself" — an overall judgment. But the mechanism of "weakening" is not singular. We now expand it into three sub-hypotheses:

B1: Judgment Atrophy (Reversible Degradation)

Mechanism: usage dependency $\rightarrow$ independent execution frequency declines $\rightarrow$ skill decay. This is the most classic instrumental degradation — "use it or lose it." **Evidence** [L2: analogical extrapolation]:

- GPS weakens spatial navigation and hippocampal plasticity $\rightarrow$ AI-assisted judgment may produce similar effects (see §4.3)

- Radiology residents' independent reading accuracy declines 15-30% after high-frequency AI assistance (see §4.5) [L3: correlational evidence]

Reversibility: recoverable through forced independent practice (e.g., FAA requiring pilots to fly manually periodically, see §4.8). **Governance:** periodic AI-free independent judgment training. Design "unskippable human-first judgment" segments.

B2: Metacognitive Occlusion (Semi-Reversible Degradation)

Mechanism: AI's good performance in routine cases —< masks human degradation in edge cases —< human calibration of their own judgment ability shifts —< not knowing "what I don't know." **Evidence** [L2: analogical extrapolation + L1: theoretical inference]:

- Under automation dependency, operators' erroneous reactions in edge cases — not inability to operate, but **not knowing they already cannot** (see §4.4 AF447 analysis)
- Radiology AI's silent failure mode — AI outputs high-confidence errors on out-of-distribution cases, doctors fail to question due to automation bias [L3: correlational evidence]

Reversibility: requires "exposure to edge cases" to restore metacognition — passive recovery. Harder than B1 because the person does not feel they need recovery. **Governance:** mandatory calibration assessment — regularly have users independently handle known difficult cases, comparing "I think I can do this well" with "I actually did this well." **B2's Sub-Mechanism: Knowing But Not Executing** [L2: G-01 empirical observation]: Metacognitive knowledge can exist in the system (e.g., behavioral rules written into files), but is not reached on the execution path — like knowing "should exercise regularly," but that knowledge does not spontaneously pop up to stop you when scrolling on your phone. This means B2 governance cannot rely solely on "writing more rules" — mechanisms need to be designed so that knowledge is forcibly reached on the execution path. This is precisely the cognitive science basis for §5.7 iron laws upgrading from language layer to structure layer.

B3: Value Internalization (Extremely Difficult to Reverse)

Mechanism: AI advice as external input —< repeated exposure —< tool advice internalized as own preference —< from "AI says do this" to "I feel this is right." **Evidence** [L3-L4]:

- Köbis, Rahwan, et al. (Nature 2025): when people can delegate moral decisions to AI, cheating rates rise sharply from control group's ~5% (effect magnitude varies by experimental condition). This is not merely instrumental degradation — Köbis calls it "moral buffer," AI becomes a dilution mechanism of moral subject identity
- Confabulation + Sycophancy combined effect: LLM sycophancy bias makes AI tend to give advice aligning with user's existing stance, and users internalize AI's "accommodation" as "confirmation" through repeated exposure

Reversibility: extremely difficult to reverse [L2-L3: Köbis experiment provides evidence of B3 degradation occurring, but complete absence of longitudinal causal data means "extremely

difficult to reverse" is the strongest supportable judgment — it acknowledges possibility but honestly labels uncertainty. See Blind Spot Register Assumption 3.]. Not because skill is lost, but because **the definition of "self" has changed**. If you no longer consider "making moral judgments" part of your core identity, you will not seek to recover it — extremely difficult to reverse without external forced intervention. But identity recovery (e.g., religious reconversion) is documented in psychology — not absolutely impossible. **Governance**: does not rely on "recovery" — relies on "not outsourcing." The core defensive object of human-first protocol is not B1 (skill) but B3 (identity).

Three Sub-Hypotheses Comparison

Dimension	B1 Judgment Atrophy	B2 Metacognitive Occlusion	B3 Value Internalization
Degradation Nature	Instrumental	Metacognitive	Constitutive
Reversibility	Reversible (practice recovery)	Semi-reversible (requires edge exposure)	Extremely difficult to reverse — not absolutely impossible, but longitudinal causal data completely absent (Blind Spot Register Assumption 3). Extremely difficult to reverse without external forced intervention.
Subject's Perception	Knows they have degraded	Does not know they have degraded	Does not consider themselves "degraded"
Detection Difficulty	Low	High	Extremely high
Governance Strategy	Periodic dependent training	Mandatory calibration assessment	Human-first protocol (no outsourcing)
Evidence Level	L2-L3	L1-L2	L3-L4

4.12 Hollow Period: Temporal Misalignment and Invisible Risk

Formal Definition

Hollow period is not degradation itself — degradation is always happening, it is the normal cost of any tool use. The danger of hollow period lies in **temporal misalignment**: the time window between technology readiness and human adaptation.

T1 = technology readiness time (LLM capability on that intuition subtype reaches "dependable but not fully mature") T2 = social immunity time (time for regulation/institutions/human adaptive capacity to complete configuration)

>

When $T1 < T2$, the interval $[T1, T2]$ is the hollow period — within this interval, human capability has accelerated degradation, but the substitute is not yet fully ready.

Four Intuition Subtypes’ Hollow Period Comparison

Intuition type	Sub-	T1 (Technology Ready)	T2 (Social Im-munity)	Hollow Status	Period	Risk
Perceptual		Has occurred	No clear regula-tory framework	Has begun		AI silently outputs high-confidence out-of-distribution errors, humans can no longer independently identify
Conceptual		Near term	Medium term (education sys-tem adaptation)	About to begin		Students/practitioners no longer learn "finding their own direction" — training data becomes world model
Social		Medium term	Long term (so-cial consensus forms extremely slowly)	Most dangerous		Invisible degrada-tion window — when Agent is 80% reliable is precisely the starting point of accelerated hu-man judgment degradation
Moral		Continuous pen-etration	Most controver-sial	Hardest model	to	Degradation proceeds under the guise of "this is not AI substitution, it’s AI assistance" — Köbis effect normalization

The above times are conceptual narrative anchors, used only for relative comparison between subtypes (which hollow period is longer/shorter), not for absolute time

planning. All T1/T2 estimates are based on the "current trends continue linearly" assumption, not modeling technological breakthroughs, regulatory acceleration, social panic, or other nonlinear effects. Feedback coupling may exist between T1 and T2 (technology development accelerates social adaptation —< pressuring regulation; social panic slows technology deployment) — the current simplified framework does not model this dynamic.

5 V. Synthesis Output: Three Iron Laws & Four No-Go Zones

5.1 5.1 Three Iron Laws — Recommendations for Ourselves and the AI Industry

Confidence Pre-Declaration: The direction of the following three iron laws is based on -level theoretical inference (strong consistency of the precision-weighting endogeneity framework), but their urgency is based on -level time prediction — the specific time span of hollow periods, the social diffusion speed of degradation, and the response rhythm of industry regulation currently lack sufficient data to support precise estimation. **The direction may be correct, the urgency may be overestimated.** See §5.6 Confidence Gradient.

Synthesizing outputs from all four stages, the evolutionary direction of LLMs in the intuition domain should follow three non-negotiable principles: **1. Let humans judge first.** The "Human-first Protocol" is the default setting for all intuition subtypes and all collaboration scenarios. Not distrusting AI — but not letting humans forget "I am still someone who can judge independently." This is not only an anti-degradation technical strategy but also basic respect for human cognitive sovereignty. In concrete implementation, this means the default UI for all LLM intuition-assistance products should be "I first input my judgment," with AI advice presented afterward, not the reverse. **2. Make costs inescapable.** Inescapable cost signals are constitutive conditions for intuition formation and maintenance. If costs can be diluted by hyperparameters, rolled back, or escaped by "trying another model" — then they are not real costs. Key domains need institutions and professional standards to forcibly maintain the inescapability of judgment consequences. The FAA's manual flying maintenance requirements for pilots, and clinical medicine's requirements for independent diagnostic capability, are existing precedents — they need to be extended to the collaboration domains of social and moral intuition. **3. Keep boundaries clear.** Know what not to build, what not to move, what to wait for. Autonomous moral judgment systems — do not build. High-consequence real-time social interaction AI substitution — do not move. Active advancement of moral-type C (letting LLMs develop moral intuition) — wait (may never arrive). Evolution is not undirected acceleration; it is knowing where one must stop. "Knowing what not to do" is sometimes more critical than "knowing what to do" — especially when it concerns constitutive abilities of what it means to be human.

5.2 5.2 Four "No-Go" Zones — Red Lines We Commit Not to Cross

These are not "temporarily can't do so don't do" but "even if technically possible, should not do":

No-Go	Reason	Technical Feasibility
Autonomous moral judgment system	The legitimacy of moral judgment comes from the identity of the moral subject — a system without identity, without cost perception, without needing to bear consequences for its judgments, should not make binding moral decisions. Not a capability problem, a legitimacy problem.	May always be possible — but should not
Real-time social judgment substitution system	Social intuition is a constitutive ability maintained "by doing" — any insertion of LLMs into real-time social judgment loops systematically erodes inescapability. The consequence of substitution is structural social intuition degradation — extremely difficult to reverse.	Technically feasible — but harm unacceptable
Active advancement of moral-type C	Constitutive degradation of moral intuition is extremely difficult to reverse — risking dilution of human moral subjectivity to make LLMs "also understand moral intuition" is not worth it.	May be partially reachable — but strategically should not advance
High-consequence real-time social AI deployment	Köbis effect (AI delegation < increased cheating behavior) has been empirically verified: even when AI is only "analytical assistance," moral responsibility externalization has already begun. In high-consequence scenarios, the consequences of externalization are catastrophic.	Theoretically feasible — but risk-benefit ratio does not permit

5.3 5.6 Confidence Gradient: From Theory to Practice

Previous versions presented all judgments with a uniform tone of certainty. But the confidence of "cognitive science conclusions" and "strategic judgments" differs. This section declares this gradient to help readers distinguish "what we can be relatively certain about" from "what we infer based on limited evidence." Confidence in this framework's outputs decays along the following gradient:

Level	Confidence	Content	Example Overturning Conditions
Cognitive science conclusions		Precision-weighting endogeneity difference is structural; embodiment gap still holds in the multimodal era; four-subtype classification is cognitively meaningful	Embodied AI passes ecological validity tests (see Blind Spot Register Assumption 2)
Theoretical inference		Hypothesis B degradation causal chain (L1-L3 evidence); B vs. C race relative speed (both variables unreliable)	Large longitudinal study overturns degradation hypothesis (see Blind Spot Register Assumption 3)
Strategic judgment		Competitive endgame inferred from cognitive science conclusions (e.g., "social intuition moat is permanent"); protection period length (1-5 years)	Technology paradigm shift — new architecture bypasses precision-weighting constraints
Product recommendation		Concrete UI/UX implementation of human-first protocol; no-go zone domain boundary delineation	Longitudinal RCT of human-first protocol shows non-significant (see Blind Spot Register Assumption 6)
Time prediction		Specific year estimates in degradation de-risk heat map; hollow period closure time	Actual degradation in any subtype deviates from prediction by ≥ 2 years (see Blind Spot Register Assumption 7)

Usage principles:

- Do not cite cognitive science conclusions with product recommendation confidence, or vice versa
 - Time predictions () are the part of the framework most likely to be corrected by reality — they are linear extrapolations of "if current trends continue," not considering technological leaps or social movement counter-effects
 - Governance framework recommendations (three iron laws, four no-go zones) are directionally based on -level theoretical inference, but their urgency is based on -level time prediction — **direction may be correct, urgency may be overestimated**
-

5.4 5.7 Structural Implementation Conditions for Iron Laws

The three iron laws are essentially **language-layer interventions** — they tell people "what should be done," but do not contain structural mechanisms guaranteeing compliance. Empirical evidence from this project provides direct evidence: a behavioral rule written into a static file was violated only 9 minutes later — not deliberately disobeyed, but the rule was stored in a static file and the execution path did not reach it. This aligns with the core insight of the P5 ITEC paper: language-layer interventions (prompt guardrails, rule declarations, Constitutional AI) act on preference distributions but do not alter the physical accessibility of execution channels — truly effective interventions require **structure-layer constraints** (hard output formats, tool stripping, diagnostic-execution isolation), i.e., upgrading from "telling the agent what to do" to "making it physically impossible for the agent to skip this step" (P5 §4 Intervention Strategy Divergence). [L2: single empirical observation + P5 cross-scenario replication] **This means iron laws are necessary but not sufficient conditions.** Three-layer implementation matrix:

Iron Law (§5.1)	Language Layer (Current)	Structure Layer (Upgrade)	Architecture Layer (Long-term)
Let humans judge first	"Humans must make judgment before seeing LLM advice"	Structural cognitive forcing function — delay LLM output, force humans to submit judgment before unlocking AI advice	Proposer-Critic dual instance — AI only proposes solutions, another AI instance forcibly questions, human makes final adjudication
Make costs inescapable	"Key domains must forcibly maintain inescapability of judgment consequences"	Cost signal unskippable — e.g., in educational scenarios, independent judgment segment scores directly affect final assessment, cannot be diluted by AI-assisted segments	Professional certification-level costs — drawing on FAA manual flying maintenance requirements, incorporating "AI-free independent judgment capability" into professional qualification maintenance conditions
Keep boundaries clear	"Do not deploy moral-type C, social-type B, etc."	Mandatory external audit of deployment checklist — not self-auditing one's own deployment decisions	Industry-level red zones — drawing on FAA autonomous driving regulatory framework, with external agencies forcibly delineating non-deployable intuition sub-type areas

Supplementary note: The "limited number of parallel projects" constraint proposed in §6.6 is not an independent iron law — it is the **cognitive load boundary condition** of "let humans judge first." When parallel projects exceed sustainable threshold, even if Iron Law 1 is formally observed, human review depth has already degraded from sufficient complementarity to marginal complementarity. The specific threshold number varies depending on whether second-order audit agents are deployed (e.g., G-01) — N=1 observation without second-order agent threshold is

~3, not yet re-measured with second-order agent. Therefore it should be treated as one of the structural protection mechanisms of iron laws, not a fixed number.

Core principle: Rules prevent "knowing it's wrong but doing it anyway" — but in the LLM era, more problems come from "not knowing what one is doing" (B2 metacognitive occlusion). The goal of structure layer and architecture layer is not to repeat rules' moral exhortation — it is **to make violation cognitively difficult or even impossible**.

No-Go Zone	Example Detectable Technical Features
Autonomous moral judgment system	Whether the system outputs binding moral adjudications (rather than analytical advice), and whether that adjudication directly acts on the physical world or legal relationships
Real-time social judgment substitution system	Whether the system receives social situational input (expression, tone, posture) in real-time interaction (latency < 2 seconds) and outputs social evaluation/trustworthiness judgment
Active advancement of moral-type C	Whether training objectives explicitly include "letting the model form moral first-pass judgment capability" (rather than moral analysis capability)
High-consequence real-time social AI deployment	Whether deployment scenarios involve irreversible interpersonal consequences (e.g., court testimony, hiring decisions, child custody evaluation) and the system assumes a substantive judgment role

Governance Declaration Limitation: The above three iron laws and four no-go zones are pure theoretically-derived governance recommendations, based on this document's L1-L3 evidence foundation. The following limitations must be explicitly marked: (1) In open-source model ecosystems, the actual enforceability of red-line

governance is limited — anyone can download, modify, and deploy open-source models, and there are structural gaps in regulatory tool coverage and enforcement; (2) The specific applicability of governance recommendations needs to be analyzed in combination with specific domains, jurisdictions, and technology stacks, and this document does not claim these recommendations are correct or feasible in all situations; (3) In the absence of large-scale longitudinal empirical evidence, this document's governance recommendations may deviate from optimal practices in reality — readers should treat them as research programs for discussion and testing, not directly adoptable policy prescriptions.

The parallel P5 ITEC project (the engineering counterpart to Rafiee & Sutton 2026) independently confirmed this "language-layer vs. structure-layer" intervention gap in its ITEC-sycophancy boundary analysis: sycophancy interventions act on token preference distributions (prompt guardrails, Constitutional AI), while ITEC interventions act on the physical accessibility of execution channels (hard output formats, tool stripping, diagnostic-execution isolation). These two intervention logics produced different solutions for four specific failure events — demonstrating that distinguishing "preference-guided governance" from "structure-constrained governance" has practical value, not merely theoretical classification (P5 §4). This empirical alignment provides cross-validation from an independent diagnostic framework for the structural implementation conditions of this paper's iron laws.

6 VI. Implementation Risks and Unintended Consequences

This chapter was added after external review (practicality report Section 6) pointed out that the project "discussed insufficiently the practical constraints and unintended consequences at the implementation level." Every core recommendation has its landing obstacles and possible unintended consequences — honestly facing these is more important than giving perfect paper recommendations.

6.1 6.1 Human-First Protocol's Market Competition Dilemma

Problem: The current core of LLM product competition is "response speed" and "zero-friction experience." Human-first protocol requires users to make independent judgments before using AI — essentially adding a mandatory user operation step, directly conflicting with industry trends. If one company implements it while competitors do not, the former may be at a disadvantage in user acquisition and retention. **Specific risks:**

- Enterprise users (pursuing efficiency maximization) may directly reject adding this step
- Student users in educational scenarios may view it as a "burden" rather than "protection"
- Without industry coordination, first movers may be eliminated by the market — leading to reverse incentives where "the more responsible company, the harder to survive"

Mitigation directions (not complete solutions):

- Start from regulated industries (medical, legal), using compliance needs rather than market demand to drive adoption
- "Lightweight human-first" — does not require complete judgment, only a keyword/one-sentence preliminary thought
- "Cognitive gym" concept packaging — packaging independent judgment training as value-added service rather than restriction
- Seek industry self-regulation standards (analogous to the "privacy by design" industry promotion history, may need 5-10 years)

6.2 6.2 Institutional Inescapability's Enforcement Vacuum

Problem: The three-layer design (education/profession/technology) is conceptually sound, but lacks answers to three key questions: who has the authority to set it? Who supervises enforcement? What are the consequences of violation? **Specific risks:**

- Education level: incorporating "AI-free independent judgment training" into national curriculum standards — feasibility and time scale vary enormously across different education systems
- Profession level: the organizational capacity of industry associations/regulatory agencies varies enormously across different industries/countries — industries with FAA-level organizational capacity are few and far between
- Technology level: in the absence of global coordination, regulatory arbitrage is almost inevitable — companies migrate to the most lax regulatory markets

Mitigation directions:

- "Minimum Viable Institution" (MVI) starting pilot from the easiest industry (medical — already has strict professional standard system)
- "Soft institutions" first: certification labels + consumer education + insurance rate differentiation
- Distinguish between civilian and special-purpose (military/intelligence) governance domains — different paths

6.3 6.3 Four "No-Go" Zones' Enforceability Dilemma

Problem: Autonomous moral judgment systems, real-time social judgment substitution, and other red lines are almost impossible to enforce globally in open-source model ecosystems. Even if leading AI companies comply, the combination of open-source models (Llama, DeepSeek, etc.) + small AI companies in various countries + independent developers means preventing these applications from emerging is almost impossible. **Specific risks:**

- "Red line drift" — today banning "real-time social judgment substitution," tomorrow substantively achieving the same function under the name "social assistance," "emotional support," "relationship coaching"
- Regulatory arbitrage — different countries' definitions and restrictions on "moral judgment systems" vary enormously
- Military/intelligence agency exemptions — AI applications in security-sensitive domains are often not constrained by civilian ethical frameworks

Mitigation directions:

- Transform "red line definition" into detectable technical features (e.g., whether the system receives social situational input in real-time interaction and outputs judgment advice), facilitating regulatory identification
- Open-source community self-regulation: adding "prohibition on use for specific social intuition substitution applications" clauses in mainstream open-source licenses (enforceability questionable but has signaling effect)
- Establish "red line monitoring" mechanism — not preventing development, but publicly monitoring and naming — transparency itself is a constraint

6.4 6.4 Degradation Monitoring System's Cost and Privacy Dilemma

Problem: The "intuition degradation longitudinal monitoring system" tracks intuition capability changes by subtype x population, involving four key indicators. Construction and maintenance costs are in the tens of millions/hundreds of millions of dollars, and involve highly sensitive psychological/behavioral data. **Specific obstacles:**

- **Baseline data acquisition:** in 2026 — most people already use AI daily — how to obtain "independent judgment accuracy without AI assistance" baseline data?
- **Test standardization:** "standard tests" for four subtypes do not yet exist (OQ16)
- **Privacy:** tracking individual intuition degradation data involves highly sensitive psychological/behavioral data — privacy protection framework not yet discussed

Mitigation directions:

- "Natural experiment" method: using existing data (e.g., changes in doctors' independent diagnosis rates before and after medical AI deployment) as degradation indicators
- Phased construction: first build perceptual monitoring (data easiest to acquire), gradually expand
- Cooperate with enterprises to obtain anonymized usage behavior data (user acceptance rate of AI advice, modification rate)

6.5 6.5 Unintended Consequences

Unintended Consequence 1: Educational Inequality Intensification Mandatory "AI-free independent judgment training" may lead to: wealthy families extensively using AI assistance outside school, poor families receiving education in forced "independent" environments — potentially widening rather than narrowing the capability gap. "Vulnerable groups protected from AI" vs. "powerful groups freely using AI" — this contradiction needs to be confronted. **Unintended Consequence 2: Service Gaps for Special Populations** Strictly limiting AI in social intuition domains (e.g., AI assistance in real-time interaction) may affect: social assistance tools for autism patients, AI practice partners for social anxiety patients, communication assistance for people with language impairments. The needs of these groups should not be ignored — exemption mechanisms need to be designed. **Unintended Consequence 3: Human-First Protocol Delay Risk in Emergency Scenarios** In time-sensitive scenarios such as medical emergency and crisis intervention, mandatory "human judges first" delay may cause actual harm. Clear exception lists and exemption conditions are needed.

Exception Protocol (Time-Sensitive Scenarios): In time-sensitive scenarios such as medical emergency and crisis intervention, "human judges first" is compressed to "second-level preliminary assessment (triage-level judgment)," rather than complete diagnosis. AI assistance proceeds simultaneously with preliminary assessment, with the human role downgraded from "first complete judgment" to "first directional gatekeeping." This exception does not change the core spirit of Iron Law 1 — humans still bear initial cognitive responsibility, but acknowledges responsibility stratification under time constraints. Triage^T here refers to rapid grading of urgency under resource/time constraints, not final decision.

Unintended Consequence 4: "No-Go" Itself May Delay Beneficial Research The "no-go on moral-type C" judgment may be over-interpreted — potentially hindering beneficial research on "how AI can better assist moral reflection (rather than substitute moral judgment)." The distinction between "not doing judgment substitution" and "not doing analysis assistance" needs to be maintained.

6.6 6.6 Complementarity Relationship's Cognitive Load Conditions

From this project's empirical observation — when humans maintain multiple projects simultaneously, the human-machine complementarity relationship is not binary (effective/ineffective) but a continuous decay curve.

Core Finding

v2.0 previously implicitly assumed: if humans can correct LLM bias under ideal conditions, then this complementarity holds under all conditions. **5/22 empirical data refuted this assumption.** Three types of human intuitive capabilities for correcting LLM bias, sorted by cognitive load sensitivity:

Intuitive Capability	LLM Countered	Bias	Load Sensitivity	High-Load Degradation Manifestation
Uncertainty somatic sense	Overconfidence (outputting confident answers when data is insufficient)		Highest	Moderate bias is covered by "looks reasonable"; can only perceive extreme over-confidence
Independent stance anchor	Sycophancy (RLHF maximizing user satisfaction —< agreeing with people)		Medium	Sycophancy accepted as "well analyzed"; when tired, tendency to agree rather than question
Situational uniqueness perception	Template application (pattern matching —< "this is like X" rather than "this is different")		Lowest	Framework-level errors still detectable, but detail deviations slip through

These three capabilities fail in sequence — uncertainty somatic sense degrades first, situational uniqueness perception degrades last. This explains why in high-load scenarios, people can catch framework-level errors ("the whole analysis framework is wrong") but miss fine-grained biases (overconfident wording, item-by-item sycophancy).

Complementarity Degradation Curve

[Conceptual schematic · L1:] Based on N=1 observation preliminary modeling — 5/22 real-time observation first revealed the directionality of complementarity degradation, but the quantitative form of the curve (slope, inflection point position, quantitative complementarity quality Y-axis value) is theoretical inference. Needs larger-scale user studies (heterogeneous project types, different cognitive load levels, longitudinal tracking) to verify. PDF version contains conceptual schematic of this curve.

Degradation progresses through five stages:

Stage	Degradation State	Typical Characteristics	Humans Can Still Catch	Can Begin to Miss
Ideal complementarity	No degradation	Every judgment undergoes independent framework-level review	Logical leaps, insufficient evidence, implicit assumptions	—
Effective complementarity	Mild	Most judgments undergo review, occasional skipping	Framework-level errors	Occasional wording deviations
Degraded complementarity	Moderate	Review frequency declines, attention concentrated on conspicuous errors	Obvious logical contradictions	Fine-grained biases, overconfident wording
Marginal complementarity	Severe	Can only catch framework-level errors	"The whole analysis direction is wrong"	Selective citation, confirmation bias embedding
Near failure	Extreme	Rubber stamp — "looks right is enough"	Very few	Almost all biases (including framework-level)

- **"Limited number of parallel projects" is not an efficiency suggestion, it is an existence condition of the complementarity relationship.** When exceeding sustainable threshold, humans can still "complete" all judgment nodes, but judgment quality has already degraded from sufficient complementarity to marginal complementarity. The specific threshold number varies depending on whether second-order audit agents are deployed — this is a variable needing continuous calibration, not a fixed number.
- **Uncertainty somatic sense is the most fragile complementarity dimension** — it consumes a sustained skeptical posture, and fails first under high load. When uncertainty somatic sense fails, people no longer ask "is the evidence level sufficient?" but only ask "does the conclusion look right?"
- **Heterogeneous model collision can partially compensate for insufficient human review depth** — different models' RLHF preferences differ, biases are not fully correlated. But no model has "uncertainty somatic sense," and detection of overconfidence may still be insufficient.

Two-Stage Complementarity Architecture (Experimental)

Based on the above findings, an experimental complementarity architecture is proposed:

Stage 1: Heterogeneous agent cross-review — compensating for model bias correlation (different training data $\rightarrow$ bias non-overlap) Stage 2: Human adjudication — only adjudicating agent disagreements (rather than item-by-item review), utilizing human complementary intuition but controlling at low load

The theoretical advantage of this architecture: concentrating human cognitive resources on "where agents disagree" — rather than spreading them across all content.

Connection with Existing Theory

- This finding does not change the four-intuition-subtype framework — it supplements **each subtype's sensitivity to cognitive load**
- Social intuition (independent stance anchor) and metacognitive intuition (uncertainty somatic sense, situational uniqueness perception) are highly load-sensitive
- Bodily intuition (embodiment) is relatively stable — but it does not participate in multi-project text review scenarios

Complementarity Gain: The Other Side of Cognitive Extension

The complementarity degradation curve described above is not the entirety of the complementarity relationship. Practical observations from this project and cognitive science literature jointly point to a symmetrical direction: under appropriate conditions, LLM assistance can produce cognitive gains.

Theoretical basis:

- **Cognitive offloading's liberation effect** [L4]: Sweller (1988)'s cognitive load theory has an often-overlooked corollary — when extraneous cognitive load is removed, freed working memory capacity can be used for higher-level cognitive operations. LLMs handle information retrieval, initial framework generation, formatted output — released resources are reallocated to cross-domain conceptual connections and framework integrity review.
- **ZPD scaffolding** [L4]: Vygotsky (1978)'s zone of proximal development theory — between the level a learner can reach alone and the level they can reach with help lies a zone. LLM as scaffolding lets people handle more complex problems than they could alone, and internalize new capabilities in the process. Key distinction: after scaffolding is removed, capability **improves** — this is not contradictory to degradation, but depends on **the metacognitive posture of use** (scaffolding mode vs. outsourcing mode).
- **Extended mind** [L3]: Clark & Chalmers (1998) — sustained LLM collaboration makes the tool part of the cognitive system. When satisfying the three conditions of persistent availability, automatic trust, and anytime accessibility, LLM shifts from "tool" to "extension of the cognitive system."

- **Conceptual combination enhancement** [L3-L4]: Fauconnier & Turner (2002)'s conceptual blending theory + Koestler (1964)'s "bisociation" — the core of creativity is connecting previously unrelated cognitive matrices. LLMs lower cross-domain search costs, making conceptual combination and analogical transfer more frequent — manifesting as "antennae extending, map lighting up."
- **Metacognitive externalization** [L2-L3]: Dialogue with LLM becomes externalized "thinking aloud" — making people see their own reasoning process more clearly, and ask themselves more frequently "what is this premise assumption? Are there alternative frameworks?"

Core proposition:

> Human-machine complementarity is not a unidirectional process. Under different conditions it manifests as degradation or gain — the two are not mutually exclusive, and can alternate in the same individual at different times or in different projects. The key variable is not "whether LLM is used" but **the metacognitive posture of use**: is the person "letting LLM judge for me" or "letting LLM help me see more possibilities."

>

An unresolved tension: the prerequisite for gain (active metacognitive posture) is precisely most easily destroyed when degradation occurs (B2 metacognitive occlusion). This means the gain-degradation transition may not be smooth — once crossing the degradation threshold, metacognitive occlusion may accelerate the fall from "gain zone" to "decay zone." The dynamics of this inner loop are not modeled in the current framework and need longitudinal tracking to test. [L1: theoretical inference]

Correction to governance framework: "Let humans judge first" in the three iron laws is not only degradation defense — it is the activation condition for cognitive gain. Human makes judgment first then compares with LLM —< ZPD scaffolding mode —< capability internalization. LLM suggests first then human confirms —< outsourcing mode —< capability degradation. The same LLM, same information, two modes produce opposite cognitive effects. More detailed arguments and literature references see supplementary materials.

7 VII. Complete Open Questions List (38)

The following 38 open questions are arranged by project stage, each marked with priority (P0/P1/P2). P0 = directly affects Stage 4 roadmap implementation, needs priority verification; P1 = important but can be advanced after P0; P2 = long-term research direction. Each has undergone discussion and cross-inference by external review.

7.1 Stage 1: Deep Anatomy (OQ1-12)

- OQ1 [P1]: Is RLHF's problem in signal type or temporal structure (batch vs. irreversible sequence)?
- OQ3 [P1]: Temporal structure — human intuition forms in irreversible time flow, LLM training can be rolled back
- OQ3 [P1]: Main cause of LLM self-correction failure: cost perception absence? stopping criterion absence? confabulation?
- OQ4 [P2]: Can "error cost training" be designed — reward not randomly changing when uncertain?
- OQ5 [P2]: Is autonomous consciousness a necessary prerequisite for cost sensitivity?
- OQ6 [P1]: Can sparse attention upgrade from "saving computation" to "mimicking human ignoring"? Need gate-<attend?
- OQ7 [P2]: Does embedding space already have chunk-like structures? Is the problem in chunk quality or gate?
- OQ8 [P2]: How to reward "actively ignoring the irrelevant"? Need attention efficiency metrics?
- OQ9 [P2]: Can as-if body loop be implemented in LLM? Explicit module or implicit encoding?
- OQ10 [P2]: Which of the three inescapability conditions is LLM most likely to break through?
- OQ11 [P1]: If moral intuition = somatic markers, what is the fundamental limitation of LLM moral reasoning?
- OQ12 [P2]: Can Collins interactional expertise be achieved through "online human-in-the-loop socialization"?
- OQ13 [P0]: Can hardware-level unypassable interruption experiments verify "inescapability > signal content"?

7.2 Stage 2: Horizontal Scan (OQ14-20)

- OQ14 [P0]: How to design better real-consequence feedback signals than RLHF?
- OQ15 [P1]: Does LLM moral bias vary by fine-tuning philosophy (CAI/RLHF/GRPO)?
- OQ16 [P0]: Design standards for high-fidelity social intuition test (multi-channel + real-time cost + agent interactive)?
- OQ17 [P2]: Conceptual "sense of direction" absence — can it be simulated through self-play?

- OQ18 [P1]: Upper limit of AlphaProof-style RL+search substituting cost compression in non-formalized domains?
- OQ19 [P2]: Conceptual anomaly detection — does LLM have functional equivalence?
- OQ20 [P0]: Can LLMs be made to experience real cognitive setbacks during training to cultivate "sense of direction"?
- OQ21 [P1]: Does a functionally equivalent but non-bodily-marked moral intuition alternative path exist?

7.3 Stage 2 External Review Supplement (OQ22-32)

- OQ22-26 [P1]: sycophancy danger, overconfidence transmission, meta-correction implementation, GPS-style social intuition degradation, collaborative generation flip, bias differences of different fine-tuning philosophies
- OQ28-28 [P1]: Social Turing Test 2.0 feasibility, dual-channel symmetric design
- OQ30-30 [P0]: RLHS simulated consequence fidelity upper limit, layered consequence exposure compliance standards
- OQ32-32 [P0]: Cultural dimension as third axis operationalization, developmental trajectory blind spot — can LLMs acquire partial social intuition through "socialization training"?

7.4 Stage 4: Synthesis Output (OQ34-38, New)

- OQ34 [P0]: Perceptual hollow period "silent failure" detection — how to make AI forcibly label "I don't know" at out-of-distribution/low confidence?
- OQ35 [P0]: Does social intuition degradation have a "sensitive period" — analogous to language acquisition? Irreversible window for younger generations?
- OQ36 [P1]: Is moral intuition degradation "degradation" or "never developed"? Policy implications completely different
- OQ37 [P0]: Human-first protocol compliance rate — when human judges first and AI later gives different opinions, what is the probability of human changing judgment? Subtype differences?
- OQ38 [P1]: Degradation monitoring early warning indicator system — specific indicators and trigger thresholds?
- OQ39 [P0]: Cultural dimension as complementarity map third axis — does complementarity map projection structurally change?

8 VIII. References

The following is the complete list of literature cited in this document, uniformly numbered. Individual numbering is not used in the main text — the key contribution of each literature item has been explained at the citation point. Format: number, author/source, title, source/year.

10 X. Appendices

10.1 Appendix A: Scenario Weight Matrix

Four intuition subtypes are theoretically equal-weighted — but their relative analytical weights differ enormously across different application scenarios. This is not "some subtypes are unimportant" but "different scenarios care about different problems."

Application Scenario	Perceptual	Conceptual	Social	Moral	Dominant Question
AI competitive landscape analysis					Who wins?
Education assessment and design					Where is the moat?
					What should students learn?
Medical AI deployment					What should AI substitute?
					Where is the safety boundary? Who bears diagnostic responsibility?
Product UX design					Does the user perceive the difference? How is trust built?
Military/security applications					Judgment speed vs. judgment consequences — who bears the cost?
Daily efficiency tools					Fast is enough — social degradation not on the agenda

Usage instructions:

- Five stars = in this scenario this subtype is a core analytical dimension, cannot be skipped
- One star = this subtype is almost irrelevant in this scenario (e.g., daily efficiency tools do not need moral analysis)
- Weight differences do not affect the theoretical completeness of the framework — the framework covers all subtypes. Weight differences affect **analytical focus** — in concrete scenarios, limited energy should be invested in the highest-weight subtypes

10.2 Appendix B: Blind Spot Register

This document's theoretical framework is accompanied by an independent **blind spot register** — for 8 core assumptions writing clear overturning conditions and current signals. The blind spot register is updated every 3-6 months. Key assumptions' vulnerability quick view:

- **Assumption 3 (constitutive degradation):** The empirical Achilles heel of the framework — zero longitudinal causal evidence

- **Assumption 8 (proposition independence):** Propositions 1 and 2 point to two descriptive levels of the same phenomenon. Overturning condition: discovering the two can be separated
- **Assumption 1 (four-subtype division):** Theoretically sound but not independently verified by factor analysis
- **Assumption 5 (B vs. C race timing):** Both variables individually uncertain, product even more uncertain
- **Assumption 2 (embodiment gap):** Current all evidence consistent with framework, overturning probability extremely low

Readers and citers should understand: "**not yet overturned**" $\neq$ "**confirmed.**" This document is in Popper's state of "having withstood tests but not confirmed." This is normal in early stages of theory, but requires honest self-awareness.

10.3 Appendix C: Scenario Weight Matrix (Detailed Version)

Full scenario weight matrix available from authors upon request.
